

Task 3 - Brief Explanation

The cloud flow diagram illustrates the working of the SentinelX Cloud Threat Intelligence Using NLP and Serverless Risk Scoring system. A user first logs into the SentinelX web application through a secure authentication mechanism using JWT. The application sends requests to the backend through REST APIs. The backend processes the incoming threat data using an NLP engine to identify malicious patterns and then invokes a serverless risk-scoring function to calculate the threat level. The processed results are stored securely in MongoDB Atlas. Finally, the system displays the results on the Security Dashboard and generates real-time threat alerts whenever high-risk activities are detected. The cloud architecture supports security, scalability, elasticity, and reliable data processing.
